

Tuple data type:

Tuple is a collection of homogenous data items or heterogeneous data item enclosed between the pair of round brackets.

Syntax:

```
Variable = (val1, val2, val3.....) or  
Variable = val1, val2, val3.....
```

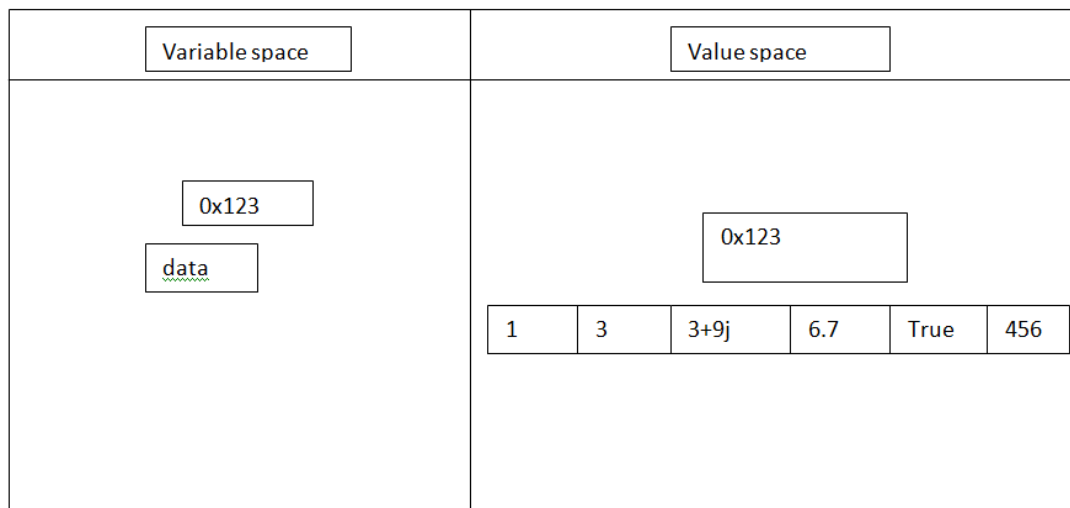

- The default value for tuple data type is (), which is internally equal to zero.
- In tuple we cannot store single value directly, to store single value the following syntax is used.

```
Variable = (val, ) or  
Variable = val,
```

E.X:

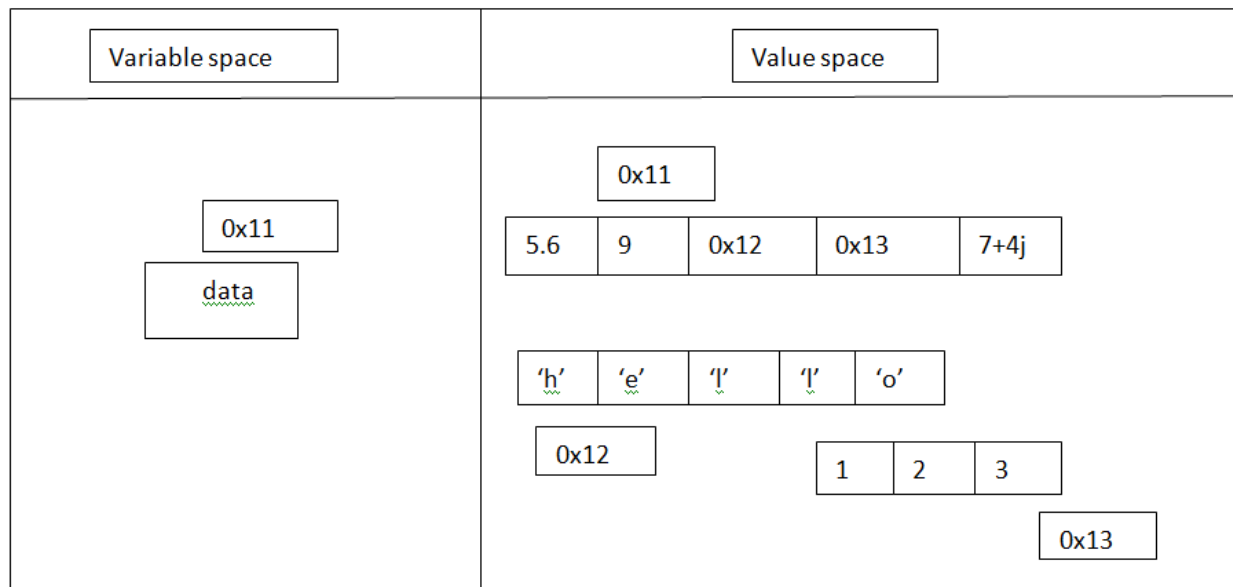

Data = (1, 3, 3+9j, 6.7, True, 456)

•

E.X:

Data = (5.6, 9, 'hello, [1, 2, 3], 7+4j')

Attributes of tuple data type:

1. **Count ()**: It is a function, which is used to count the number occurrence of the specified element.
 - Variable.count(value)
2. **Index ()**: It is a function, which is used to get the index position of the specified character.
 - Variable.index(value)

Tuple is the most secured data type, which we have in python. Because of this reason tuple is used in “secured data transmission”

Difference between tuple and list:

list	tuple
It is mutable data type.	It is immutable.
Values will be stored between pair of square brackets.	Values will be stored between pair of the round brackets.
It is possible to store single value directly.	Without comma we cannot store single value.
List is not secured.	Tuple is secured.
